(54) Title: POWDER COATING PROCESS**(57) Abstract**

A process for forming a coating on a conductive substrate, which comprises establishing a fluidised bed of a powder coating composition, immersing the substrate wholly or partly within the said fluidised bed, applying a voltage to the substrate for at least part of the period of immersion, whereby particles of the powder coating composition adhere to the substrate, withdrawing the substrate from the fluidised bed and forming the adherent particles into a continuous coating over at least part of the substrate. The process enables the coating of substrate areas which, because of the Faraday cage effect, are inaccessible in conventional electrostatic coating processes, and also enables the formation of thinner coatings than are obtainable by conventional fluidised-bed processes.

POWDER COATING PROCESS

This invention relates to a process for the application of powder coating compositions to
5 substrates.

Powder coatings form a rapidly growing sector of the coatings market. Powder coatings are solid compositions which are generally applied by an electrostatic spray process in which the powder coating
10 particles are electrostatically charged by the spray gun and the substrate (normally metallic) is earthed. The charge on the powder coating particles is normally applied by interaction of the particles with ionised air (corona charging) or by friction (tribostatic or "tribo"
15 charging). The charged particles are transported in air towards the substrate and their final deposition is influenced inter alia by the electric field lines that are generated between the spray gun and the workpiece. A disadvantage of this process is that there are
20 difficulties in coating articles having complicated shapes, and especially articles having recessed portions, as a result of restricted access of the electric field lines into recessed locations (the Faraday cage effect), especially in the case of the
25 relatively strong electric fields generated in the corona-charging process. The Faraday cage effect is much less evident in the case of tribostatic charging processes, but those processes have other drawbacks.

As an alternative to electrostatic spray processes,
30 powder coating compositions may be applied by fluidised-bed processes, in which the substrate workpiece is preheated (typically to 200°C-400°C) and dipped into a fluidised bed of the powder coating composition. The powder particles that come into contact with the

preheated surface melt and adhere to the workpiece. In the case of thermosetting powder coating compositions, the initially-coated workpiece may be subjected to further heating to complete the curing of the applied coating. Such post-heating may not be necessary in the case of thermoplastic powder coating compositions.

Fluidised-bed processes eliminate the Faraday cage effect, thereby enabling recessed portions in the substrate workpiece to be coated, and are attractive in other respects, but have the well-known disadvantage that the applied coatings are substantially thicker than those obtainable by electrostatic coating processes.

Another alternative application technique for powder coating compositions is the so-called electrostatic fluidised-bed process, in which the fluidising air is ionised by means of charging electrodes arranged in the fluidising chamber or, more usually, in the plenum chamber below the porous air-distribution membrane. The ionised air charges the powder particles, which acquire an overall upwards motion as a result of electrostatic repulsion of identically charged particles. The effect is that a cloud of charged powder particles is formed above the surface of the fluidised bed. The substrate workpiece (earthed) is introduced into the cloud and powder particles are deposited on the substrate surface by electrostatic attraction. No preheating of the substrate workpiece is required.

The electrostatic fluidised-bed process is especially suitable for coating small articles, because the rate of deposition of the powder particles becomes less as the article is moved away from the surface of the charged bed. Also, as in the case of the traditional fluidised-bed process, the powder is

confined to an enclosure and there is no need to provide equipment for recycling and reblending the overspray that is not deposited on the substrate. As in the case of the corona-charging electrostatic process, however, there is a strong electric field between the charging electrodes and the substrate workpiece and, as a result, the Faraday cage effect operates to a certain extent and leads to poor deposition of powder particles into recessed locations on the substrate.

10 The present invention provides a process for forming a coating on a conductive substrate, which comprises establishing a fluidised bed of a powder coating composition, immersing the substrate wholly or partly within the said fluidised bed, applying a voltage
15 to the substrate for at least part of the period of immersion, whereby particles of the powder coating composition adhere to the substrate, withdrawing the substrate from the fluidised bed and forming the adherent particles into a continuous coating over at
20 least part of the substrate.

In general, the process comprises the steps of establishing a fluidised bed of a powder coating composition, immersing the substrate wholly or partially within the said fluidised bed, applying a voltage to the
25 substrate for at least part of the period of immersion, whereby particles of the powder coating composition are charged substantially by friction alone and adhere to the substrate, withdrawing the substrate from the fluidised bed and forming the adherent particles into a
30 continuous coating over at least part of the substrate.

Conversion of the adherent particles into a continuous coating (including, where appropriate, curing of the applied composition) may be effected by heat treatment and/or by radiant energy, notably infra-red,

ultra-violet or electron beam radiation.

In the process of the present invention, particles of the powder coating composition adhere to the substrate as a result of the frictional charging 5 (tribostatic or "tribo" charging) of the particles as they rub against one another in circulating in the fluidised bed. As compared with processes in which a substantial electric field is generated between charging electrodes and the substrate workpiece, the process of 10 the present invention offers the possibility of achieving good coating of substrate areas which are rendered inaccessible by the Faraday cage effect.

The process of the present invention is conducted without ionisation or corona effects in the fluidised 15 bed.

The voltage applied to the substrate is sufficient to attract the frictionally charged powder coating particles to the substrate while resulting in a maximum potential gradient that is insufficient to produce 20 either ionisation or corona effects in the fluidised bed of powder coating composition. Air at atmospheric pressure usually serves as the gas in the fluidised bed but other gases may be used, for example, nitrogen or helium.

25 Since the voltage applied to the substrate is insufficient to produce either ionisation or corona effects in the fluidised bed of powder coating composition, the substrate is, in effect, electrically isolated and there is effectively no current flow in the 30 substrate. If there is any current flow, it is anticipated that it is unlikely to be more than 10 mA, probably unlikely to be more than 5 mA and expected to be less than 1mA and more likely to be of the order of a few microamps; that is, the current is, in practice,

expected to be too small to be measured by conventional current-measuring instruments.

As compared with traditional fluidised-bed application technology, the process of the invention offers the possibility of applying thinner coatings in a controlled manner since frictional charging has been found to become more efficient as particle sizes are reduced. Improvements in efficiency as particle sizes are reduced contrasts with the situation for powder coating using a triboelectric gun where efficiency falls as particle sizes are reduced. Also, compared with traditional fluidised-bed application technology, pre-heating of the substrate is not an essential step in the process of the invention.

15 The uniformity of the coating may be improved by shaking or vibrating the workpiece in order to remove loose particles.

Powder coating compositions generally comprise a solid film-forming resin, usually with one or more colouring agents such as pigments, and optionally also contain one or more performance additives.

A powder coating composition for use according to the invention will in general be a thermosetting system (incorporating, for example, a film-forming polymer and a corresponding curing agent which may itself be another film-forming polymer), but thermoplastic systems (based, for example, on polyamides) can in principle be used instead.

The film-forming polymer used in the manufacture of a thermosetting powder coating composition for use according to the invention may be one or more selected from carboxy-functional polyester resins, hydroxy-functional polyester resins, epoxy resins, and functional acrylic resins.

The composition may, for example, be based on a solid polymeric binder system comprising a carboxy-functional polyester film-forming resin used with a polyepoxide curing agent. Such carboxy-functional polyester systems are currently the most widely used powder coatings materials. The polyester generally has an acid value in the range 10-100, a number average molecular weight M_n of 1,500 to 10,000 and a glass transition temperature T_g of from 30°C to 85°C, preferably at least 40°C. The poly-epoxide can, for example, be a low molecular weight epoxy compound such as triglycidyl isocyanurate (TGIC), a compound such as diglycidyl terephthalate or diglycidyl isophthalate, an epoxy resin such as a condensed glycidyl ether of bisphenol A or a light-stable epoxy resin. Such a carboxyfunctional polyester film-forming resin can alternatively be used with a bis(beta-hydroxyalkylamide) curing agent such as tetrakis(2-hydroxyethyl) adipamide.

Alternatively, a hydroxy-functional polyester can be used with a blocked isocyanate-functional curing agent or an amine-formaldehyde condensate such as, for example, a melamine resin, a urea-formaldehyde resin, or a glycol ural formaldehyde resin, for example, the material "Powderlink 1174" supplied by the Cyanamid Company, or hexahydroxymethyl melamine. A blocked isocyanate curing agent for a hydroxy-functional polyester may, for example, be internally blocked, such as the uret dione type, or may be of the caprolactam-blocked type, for example, isopherone diisocyanate.

As a further possibility, an epoxy resin can be used with an amine-functional curing agent such as, for example, dicyandiamide. Instead of an amine-functional

curing agent for an epoxy resin, a phenolic material may be used, preferably a material formed by reaction of epichlorohydrin with an excess of bisphenol A (that is to say, a polyphenol made by adducting bisphenol A and an epoxy resin). A functional acrylic resin, for example a carboxy-, hydroxy- or epoxy-functional resin can be used with an appropriate curing agent. Mixtures of binders can be used, for example a carboxy-functional polyester can be used with a carboxy-functional acrylic resin and a curing agent such as a bis(beta-hydroxyalkylamide) which serves to cure both polymers. As further possibilities, for mixed binder systems, a carboxy-, hydroxy- or epoxyfunctional acrylic resin may be used with an epoxy resin or a polyester resin (carboxy- or hydroxy-functional). Such resin combinations may be selected so as to be co-curing, for example, a carboxy-functional acrylic resin co-cured with an epoxy resin, or a carboxy-functional polyester co-cured with a glycidyl-functional acrylic resin. More usually, however, such mixed binder systems are formulated so as to be cured with a single curing agent (for example, use of a blocked isocyanate to cure a hydroxy-functional acrylic resin and a hydroxyfunctional polyester). Another preferred formulation involves the use of a different curing agent for each binder of a mixture of two polymeric binders (for example, an amine-cured epoxy resin used in conjunction with a blocked isocyanate-cured hydroxy functional acrylic resin).

Other film-forming polymers which may be mentioned include functional fluoropolymers, functional fluorochloropolymers and functional fluoroacrylic polymers, each of which may be hydroxy-functional or carboxy-functional, and may be used as the sole film-

forming polymer or in conjunction with one or more functional acrylic, polyester and/or epoxy resins, with appropriate curing agents for the functional polymers.

Other curing agents which may be mentioned include epoxy phenol novolacs and epoxy cresol novolacs; isocyanate curing agents blocked with oximes, such as isophorone diisocyanate blocked with methyl ethyl ketoxime, tetramethylene xylene diisocyanate blocked with acetone oxime, and Desmodur W (dicyclohexylmethane diisocyanate curing agent) blocked with methyl ethyl ketoxime; light-stable epoxy resins such as "Santolink LSE 120" supplied by Monsanto; and alicyclic polyepoxides such as "EHPE-3150" supplied by Daicel.

A powder coating composition for use according to the invention may be free from added colouring agents, but usually contains one or more such agents (pigments or dyes) and can contain one or more performance additives such as a flow-promoting agent, a plasticiser, a stabiliser, for example a stabiliser against UV degradation, an anti-gassing agent, such as benzoin, a filler, or two or more such additives may be present in the coating composition. Examples of pigments which can be used are inorganic pigments such as titanium dioxide, red and yellow iron oxides, chrome pigments and carbon black and organic pigments such as, for example, phthalocyanine, azo, anthraquinone, thioindigo, isodibenzanthrone, triphendioxane and quinacridone pigments, vat dye pigments and lakes of acid, basic and mordant dyestuffs. Dyes can be used instead of or as well as pigments.

A pigment content of $\leq 40\%$ by weight of the total composition (disregarding dry blend additives) may be used. Usually a pigment content of 25-30% is used, although in the case of dark colours opacity can be

obtained with < 10% by weight of pigment. Where appropriate, a filler may be used to assist opacity, whilst minimising costs.

A powder coating composition used in the process of the invention may be formulated in accordance with normal practice and, in particular, it is possible to use compositions formulated especially for corona-charging application as well as compositions formulated especially for tribo-charging application (for example, for the latter, by the use of suitable polymers of which the so-called "tribo-safe" grades are an example or by the use of additives which can be introduced prior to extrusion in a manner known per se).

The powder coating composition may incorporate, by dry-blending, one or more fluidity-assisting additives, for example, those disclosed in WO 94/11446, and especially the preferred additive combination disclosed in that Specification, comprising aluminium oxide and aluminium hydroxide. Other dry-blended additives which may be mentioned include aluminium oxide and silica, either singly or in combination.

The total content of dry-blended additive(s) incorporated with the powder coating composition will in general be in the range of from 0.01% to 10% by weight preferably at least 0.1% by weight and not exceeding 1.0% by weight (based on the total weight of the composition without the additive(s)).

The voltage applied to the substrate in the process of the present invention is preferably a direct voltage, either positive or negative, but an alternating voltage is also usable in principle. The applied voltage may vary within wide limits according, inter alia, to the size of the fluidised bed, the size and complexity of the workpiece and the film thickness desired. On this

basis, the applied voltage will in general be in the range of from 100 volts to 100 kilovolts, more usually from 200 volts to 60 kilovolts, preferably from 300 volts to 30 kilovolts, more especially from 500 volts to 55 kilovolts, both positive and negative when a direct voltage is used.

Other possible voltage ranges include 5 to 60 kilovolts, 15 kilovolts to 35 kilovolts, 5 kilovolts to 30 kilovolts and 30 kilovolts to 60 kilovolts, both 10 positive and negative when a direct voltage is used.

In each case, ionisation and corona conditions may be excluded by so selecting the voltage range according to the spacing of the substrate from elements of the apparatus as to cause a maximum potential gradient below 15 30 kV/cm., the ionisation potential gradient for air at atmospheric pressure, when air serves as the gas in the fluidised bed, operation usually being at atmospheric pressure. Either nitrogen or helium, for example, instead of air, could serve as the gas in the fluidised 20 bed and, for operation at about atmospheric pressure, a maximum potential gradient below 30 kV/cm would be suitable for use with those gases.

The voltage may be applied to the substrate before it is immersed in the fluidised bed and not disconnected 25 until after the substrate has been removed from the bed.

Alternatively, the voltage may be applied only after the substrate has been immersed in the fluidised-bed. Optionally, the voltage may be disconnected before the substrate is withdrawn from the fluidised-bed.

30 The substrate will usually be wholly immersed within the fluidised bed.

The preferred period of immersion of the workpiece in a charged condition will depend on the size and geometrical complexity of the substrate, the film

thickness required, and the magnitude of the applied voltage and will generally be in the range of from 30 seconds to 5 minutes.

Preferably, the substrate is moved in a regular or intermittent manner during its period of immersion in the fluidised bed. The motion may, for example, be linear, rotary and/or oscillatory. As is indicated above, the substrate may, additionally, be shaken or subjected to vibration in order to remove particles adhering only loosely to it. As an alternative to a single immersion, the substrate may be repeatedly immersed and withdrawn until the desired total period of immersion has been achieved.

The pressure of the fluidising gas (normally air) will depend on the bulk of the powder to be fluidised, the fluidity of the powder, the dimensions of the fluidised bed, and the pressure difference across the porous membrane, and will generally be in the range of from 0.1 to 5.0 bar. Possible ranges include 0.5 to 4.0 bar and in certain circumstances 2.0 to 4.0 bar would be suitable.

The particle size distribution of the fluidised powder coating composition may be in the range of from 1 to 120 microns, with a mean particle size within the range 15 to 75 microns, preferably 25 to 50 microns, more especially 20 to 45 microns.

Finer size distributions may be preferred, especially where relatively thin applied films are required, for example, compositions in which one or more of the following criteria is satisfied:

- a) 95-100% by volume < 50 μm
 - b) 90-100% by volume < 40 μm
 - c) 45-100% by volume < 20 μm
 - d) 5-100% by volume < 10 μm
 - 5 preferably 10-70% by volume < 10 μm
 - e) 1-80% by volume < 5 μm
 preferably 3-40% by volume < 5 μm
 - f) $d(v)_{50}$ in the range 1.3-32 μm
 preferably 8-24 μm
- 10 The thickness of the applied coating may be in the range of from 5 to 200 microns or 5 to 100 microns, more especially from 10 to 150 microns, possibly from 20 to 100 microns, 60 to 80 microns or 80 to 100 microns or 50 to 150 microns, advantageously 50 microns or less, and
- 15 preferably from 15 to 40 microns. The principal factor affecting the thickness of the coating is the applied voltage, but the duration of the period of immersion in charged condition also has an influence.
- The substrate comprises metal (for example, 20 aluminium or steel) or another conductive material, and may in principle be of any desired shape and size. Advantageously, the substrate is chemically or mechanically cleaned prior to application of the composition, and, in the case of metal substrates, is preferably
- 25 subjected to chemical pre-treatment, for example, with iron phosphate, zinc phosphate or chromate.
- The process of the invention offers particular benefits in the automotive and other fields where it is desired to coat an article such as a car body at
- 30 sufficient film build to provide adequate cover for any metal defects before applying an appropriate topcoat. According to previous practice, it has been necessary to

apply two separate coats to such articles in order to provide proper preparation for the topcoat. Thus, it has been common practice to apply a first coating of an electropaint to give a barrier film over the whole metal surface, followed by a second coating of a primer surfacer to ensure proper covering of any visible defects. By contrast, the present invention offers the possibility of achieving adequate protective and aesthetic coverage, even of articles of complex geometry, by means of a single coating applied by the process of the invention. Also, the coating process can be adapted to produce relatively high film thicknesses in a single operation if required.

The invention accordingly also provides a process for coating automotive components, in which a first coating derived from a powder coating composition is applied by means of the process of the invention as herein defined, and thereafter a topcoat is applied over the powder coating.

Mention should also be made of applications of the process of the invention in the aerospace industry, where it is of particular advantage to be able to apply uniform coatings at minimum film weights to substrates (especially aluminium or aluminium-alloy substrates) of a wide range of geometric configurations in an environmentally-compliant manner.

The process of the invention is capable of dealing with articles such as wire baskets and freezer shelves which include welds and projections, providing a uniform coating of powder on the welds and projections as well as on the remainder of the articles. Alternative coating processes, in contrast, may be expected to yield non-uniform coatings on articles such as wire baskets and freezer shelves since, with the alternative coating

processes, adequate covering of welds is often achieved only with over-covering of the projections.

Advantageously, the fluidised bed is provided with an electrical connection, serving as the source of the reference or "earth" voltage for the remainder of the apparatus. If no connection is provided, it may be found that the coating performance of the fluidised bed deteriorates more quickly than would otherwise be the case. For safety reasons, the fluidised bed is, preferably, connected to the earth terminal of the electrical mains supply (referred to as an earth connection) energising the apparatus.

Advantageously, to minimise charge leakage, the connection to the substrate is not an earth connection.

In one form of process according to the invention, one or more counter-electrodes, preferably connected to the earth terminal of the electrical mains supply energising the apparatus, are disposed within the bulk of the fluidised powder coating composition. The counter-electrodes may be charged instead of being connected to the earth terminal of the mains supply.

The counter-electrodes serve to improve the efficiency of the process according to the invention, in the coating of a substrate with recesses, for example, by so modifying the electric field within the recesses, on insertion into the recesses, as to cause greater penetration of the electric field into the recesses, thereby effecting an increase in the amount of powder attracted into the recesses. Care is taken to ensure that separations between the counter-electrodes and the substrate in relation to the voltage applied to the substrate are always such that the maximum potential

gradient between a counter-electrode and the substrate lies below 30 kV/cm, the ionisation potential for air at atmospheric pressure, when air at atmospheric pressure serves as the gas in the fluidised bed. That is, the process of the invention continues to be conducted without ionisation or corona effects in the fluidised bed when counter-electrodes are used. As is indicated above, either nitrogen or helium, for example, may be used as the fluidising gas with substantially no change to the electrical conditions in the fluidised bed.

The quantity of the powder coating composition deposited on the substrate or a series of substrates is relatively very small as compared with the quantity of the composition in the fluidised bed. Some replenishment may, however, be desirable from time to time.

As is stated above, in the process according to the invention, the charging of the powder particles is effected by natural friction between particles in the fluidised-bed. The friction between the particles in the fluidised-bed leads to bipolar charging of the particles, that is to say, a proportion of the particles will acquire a negative charge and a proportion will acquire a positive charge. The presence of both positively and negatively charged particles in the fluidised-bed may appear to be a disadvantage, especially in the preferred case in which a direct voltage is applied to the substrate, but the process of the invention is capable of accommodating the bipolar charging of the particles.

In the case in which a direct voltage of a given polarity is applied to the substrate, electrostatic forces will tend to attract predominantly oppositely

-charged powder coating particles onto the substrate. The resulting removal of positively and negatively charged particles at different rates leads to a progressive reduction in the proportion of the oppositely-charged species in the bulk powder which, if uncorrected, will result in such charge distribution imbalance as to reduce the coating efficiency for successive substrates over time.

A further consequence of a significant charge distribution imbalance among the powder coating particles is that a proportion of the non-oppositely-charged powder coating particles in the fluidised-bed will tend to deposit on the walls of a fluidising chamber in which the bed is established. Continued deposition of that kind will result in the progressive accumulation of an insulating layer of powder and, as a consequence, coating efficiency will be impaired. It is possible in principle to alleviate that problem by mechanical removal of the deposited powder, with the removed powder thereby being re-introduced into the bulk fluidised composition. Such mechanical cleaning, however, is not completely reliable or effective and, moreover, re-introduction of the removed powder may contribute towards an undesirable charge distribution in the bulk fluidised composition. Where counter-electrodes are present, the counter-electrodes, too, may suffer from powder deposition when there is a significant charge imbalance among the powder coating particles.

It has been found that charge is most effectively removed from particles deposited on the walls of the fluidising chamber in which the fluidised-bed is established when the fluidising chamber is connected to the earth terminal of the mains power supply energising

the apparatus. Where counter-electrodes are used, charge is most effectively removed from particles deposited on the counter-electrodes when the counter-electrodes are connected to the earth terminal of the mains supply.

5 Advantageously, in a process according to the invention for coating successive substrates in sequence, direct voltage is used and the polarity of the voltage applied to successive substrates is reversed from each substrate to the next so as to produce an alternating
10 sequence. Such a process variant offers the possibility of reducing the extent of charge imbalance in the bulk fluidised powder caused by preferential deposition on the substrate of charged particles of one polarity.

Alternation of the polarity of successive
15 substrates results in a relatively balanced long-term average distribution of positively and negatively charged particles in the fluidised-bed also serves to reduce the extent of deposition of the powder on the walls of the fluidising chamber and, when used, the
20 counter-electrodes disposed in the fluidising chamber.

A further process variant taking account of the bipolar charging of the powder particles comprises the simultaneous batchwise coating of one or more pairs of substrates disposed within a common fluidised bed, the
25 substrates of each pair being charged by direct voltages to respectively opposite polarities. In that process variant, the walls of the fluidising chamber are connected to the earth terminal of the mains supply and there may be provided one or more counter-electrodes,
30 connected to the earth terminal of the mains supply, to establish a specific configuration of the electric field among the oppositely-charged substrates and the fluidising chamber.

The invention further provides a continuous process for the coating of substrates, in which a series of substrates of alternate polarities is transported through a fluidised-bed established within a fluidising chamber having walls composed alternately (in the direction of travel of the substrates) of insulating sections and conducting sections. The conducting sections of the fluidising chamber would usually be held at different voltages in order to provide different conditions in the respective sections of the chamber but it will be understood that the conductive sections would, in some circumstances, all be connected to the earth terminal of the mains supply.

In a variant of this continuous process, the alternately charged substrates are transported in sequence past an array of counter-electrodes (preferably connected to the earth terminal of the mains supply) disposed within the fluidised-bed. These continuous processes offer benefits which are similar in principle to those of the individual coating of successive substrates of alternate polarities and the simultaneous coating of pairs of substrates of respectively opposing polarities.

The invention further provides apparatus for use in carrying out the process of the invention, which comprises:

- (a) a fluidising chamber;
- (b) means for effecting fluidisation of a bulk powder coating composition within the fluidising chamber so as to establish a fluidised bed of the composition therein;
- (c) means for immersing a substrate wholly or partly within the fluidised bed;
- (d) means for applying a voltage to the

substrates for at least part of the period of immersion, whereby the substrate becomes electrically charged so that particles of the powder coating composition adhere thereto;

5 (e) means for withdrawing the substrate bearing adherent particles from the fluidised bed; and

(f) means for converting the adherent particles into a continuous coating.

10 Several forms of process in accordance with the invention, and two general forms of fluidisation and coating apparatus suitable for carrying out the process, will now be described, by way of example, with reference to the accompanying drawings (not to scale), in which:

Fig. 16 is a diagrammatic perspective view of an arrangement for coating a plane workpiece
5 between counter-electrodes and

Fig. 17 is a plan view of the arrangement of Fig. 16 positioned on a fluidising chamber.

Referring to Fig. 1 of the accompanying drawings,
10 the fluidisation and coating apparatus comprises an earthed (connected to the earth terminal of the mains supply) vessel (1) having an air inlet (2) at its base and a porous air distribution membrane (3) disposed transversely so as to divide the vessel into a lower
15 plenum (4) and an upper fluidising compartment (5).

In operation, a workpiece (6) having an insulated support (7), preferably a rigid support, is immersed into a fluidised bed of a powder coating composition established in the fluidising compartment (5) by means
20 of an upwardly-flowing stream of air introduced from the plenum (4) through the porous membrane (3).

For at least part of the period of immersion, a direct voltage is applied to the workpiece (6) by means of a supply cable (8) from a variable voltage source
25 (9). The workpiece becomes electrically charged and particles of the powder coating composition adhere thereto. There are no ionisation or corona effects and, for that reason, the workpiece is substantially isolated electrically, a consequence of which is that the
30 amperage is very low.

The workpiece may be moved in a regular oscillatory manner during the coating process by means not shown in Fig. 1. Instead, the workpiece may be advanced through the bed either intermittently or continuously during

immersion, or may be repeatedly immersed and withdrawn until the desired total period of immersion has been achieved.

After the desired period of immersion the workpiece 5 is withdrawn from the fluidised bed, the applied voltage is disconnected and the workpiece is heated so as to melt and fuse the adhering particles of the powder coating composition and complete the coating.

Referring to Fig. 2, the workpiece comprises an 10 aluminium panel folded as shown to give a piece which is generally U-shaped in plan view (so as to define a central recess) and has dimensions as follows:

	a	=	75	mm
	b	=	72.5	mm
15	c	=	5	mm

The following Examples illustrate the process of the invention, and were carried out using apparatus as shown in Fig. 1 with a fluidisation unit supplied by the Nordson Corporation having a generally cylindrical 20 vessel (1) of height 25 cm and diameter 15 cm.

In each Example, the workpiece (6) was connected to the direct-current supply cable (8) by means of a crocodile clip (10) - Fig. 2 - mounted on an insulating support (7) in the form of a rod of length 300 mm. The 25 workpiece was positioned centrally within the fluidising unit, giving rise to a minimum spacing of about 3.8 cm between the workpiece and the wall of the fluidising unit and resulting in a maximum potential gradient of about 0.79 kV/cm between the workpiece and the 30 fluidising unit, when a voltage of 3 kV is applied to the workpiece. That is, satisfactory results are obtained for a maximum potential gradient that is expected to be no more than 1 kV/cm. It will be evident that the workpiece would need to be at a minimum

distance of 0.1 cm from the wall of the fluidising unit in order for the maximum potential gradient to be 30 kV/cm when a voltage of 3 kV (the maximum used) is applied to the workpiece. The maximum potential gradient at 0.5 kV, the lowest voltage used, is about 0.13 kV/cm and, as for some of the examples below, the lowest voltage may be 0.2 kV giving a maximum potential gradient of about 0.05 kV/cm. Allowing for the oscillation or the vibration of the workpiece, it is expected that satisfactory results would be obtained in conditions providing maximum potential gradients in the range 0.05 kV/cm to 1 kV/cm, probably 0.05 kV/cm to 5 kV/cm and, possibly, 0.05 kV/cm to 10 kV/cm.

Unless otherwise stated, the fluidising air pressure was 1 bar in each case.

The standard bake and cure of the deposited material in each Example comprised heating at 200°C for 5 minutes.

The particle size data reported in the Examples was determined using the Mastersizer X laser light-scattering device manufactured by Malvern Instruments.

The data is expressed in volume percentiles $d(v)X$, where X is the percentage of the total volume of the particles that lies below the stated particle size d . Thus, for instance, $d(v)_{50}$ is the median particle size of the sample. Data relating to the deposited material (before bake and cure) was obtained by scraping the adhering deposit off the workpiece and into the Mastersizer.

All dip times reported in the Examples are in seconds.

Example 1:

5

The powder coating composition used in this Example was a white epoxy polyester hybrid powder designed for corona application and formulated as follows:

10		<u>Parts by weight</u>
	Rutile Titanium Dioxide	321
	Filler (dolomite)	107
	Carboxylic Acid-Functional	
	Polyester Resin	374
15	Epoxy Resin Curing Agent	152
	Catalyst	30
	Wax	3
	Flow Modifier	10
	Benzoin	3
20		_____
		1000

25

The ingredients were dry mixed in a blender, and fed into a twin-screw extruder operating at a temperature of 108°C. The extrudate was ground in an

- 24 -

impact mill to produce a powder with the following particle size distribution:

	$d(v)_{99}$		106.11 microns
	$d(v)_{50}$		41.45 microns
5	6.31%	<	10 microns
	2.04%	<	5 microns

Before fluidisation, the composition was blended with a 0.1% by weight addition of a synthetic silica flatting (matting) agent (fumed silica TS 100 ex-10 Degussa).

Before immersion of the workpiece, the blended composition was allowed to fluidise for 30 minutes in order to reach an equilibrium state.

The workpiece was connected to the voltage source and then immersed in the equilibrated fluidised bed for a given "dip" time before being withdrawn from the bed.

While immersed, the workpiece was slowly moved back and forth in a regular oscillatory manner. The process was repeated at different applied voltages and dip times.

Table 1 below summarises the characteristics of the finished coating after standard bake and cure, for various applied voltages and dip times.

Table 1

Voltage (Volts)	Dip Time(s)	% Coverage on 5mm Recessed Panel		Film Thickness (μm)			Standard Deviation of Film Thickness (μm)
		Outer	Inner	Max.	Min.	Mean	
0	120	25	50	225	0	54	86
500	180	60	60	260	0	120	93
1000	180	75	20	387	6	194	104
1300	240	100	70	270	102	204	50
2000	60	90	45	288	8	198	84
2500	30	65	15	299	0	197	131
3000	30	45	20	400	0	211	163

In order to obtain the data relating to % coverage and film thickness, the U-shaped (recessed) panel (6) was first flattened out as far as practicable into 5 generally rectangular form as shown in Fig. 3. The central portion (11) retained some recessed character because of the difficulty of achieving an uninterrupted planar form without damaging the applied coating during the unfolding procedure.

10 Film thickness measurements were then taken at each of the points marked 'X' in Fig. 3 on both the obverse and the reverse of the flattened panel, giving a total of 18 readings for each face (corresponding to the "outer" and "inner" faces of the workpiece in the folded 15 condition (Fig. 2), and 36 readings in all.

The figure given in the Table for maximum film thickness in each experiment is the highest of the 36 readings, and the figure given for minimum film thickness is the lowest of the readings. The quoted 20 mean figure is the arithmetic mean of the 36 readings and the standard deviation is derived for each experiment from the 36 readings obtained as described.

The % coverage of each face was assessed visually.

The same procedures were used to obtain film 25 thickness and % coverage data in each of the other Examples utilising U-shaped (recessed) workpieces, and analogous procedures were used in the case of the Examples using planar workpieces.

It will be seen from Table 1 that the optimum 30 results were achieved with an applied voltage of 1.3 kV and a dip time of 240 seconds.

Fig. 6 shows the particle size distribution of the material deposited on the workpiece in Example 1, as a function of deposition voltage and dip time, as compared

with the particle size distribution of the initial powder coating composition. It will be seen that the finer particles are deposited preferentially, leading to progressive depletion of those particle sizes in the fluidised bed.

The particle size distribution of the deposited material may be summarised as follows:

	d(v) ₉₉		67.55 microns
	d(v) ₅₀		15.54 microns
10	29.58%	<	10 microns
	8.67%	<	5 microns

Example 2:

The powder coating composition used in this Example 15 was a white hybrid powder designed for tribostatic application, and formulated as follows:

		<u>Parts by weight</u>
	Rutile Titanium Dioxide	252
	Filler (Calcium Carbonate)	140
20	Carboxylic Acid-Functional Polyester Resin (Uralac P5261 ex.DSM)	360
	Epoxy Resin	230
	Flow Modifier	10
25	Wax	5
	Benzoin	3
		<hr/>
		1000
30		<hr/>

The ingredients were dry mixed in a blender, and fed into a twin-screw extruder operating at a temperature of 108°C. The extrudate was ground in an

- 27 -

impact mill to produce a powder with the following particle distribution:

	d(v) ₉₉		118.84 microns
	d(v) ₅₀		45.48 microns
5	6.06%	<	10 microns
	1.70%	<	5 microns

Before fluidisation, the composition was blended with a 0.1% addition of aluminium oxide.

The coating process was carried out as described in Example 1, except that the substrate was a planar, rectangular aluminium panel (100 mm x 60 mm) and a constant dip time of 100 seconds was used.

Table 2 below summarises the characteristics of the finished coating after standard bake and cure as a function of the applied deposition voltage.

Table 2

Voltage (Volts)	Dip Time(s)	% Coverage on (100x60)mm Flat Panel	Film Thickness (μm)			Standard Deviation of Film Thickness (μm)
			Max.	Min.	Mean	
0	150	25	62	0	41	12
500	150	60	109	0	73	26
750	150	95	109	21	61	24
1000	150	100	155	30	84	40
1500	150	100	225	75	130	47

It will be seen that the thickness of the applied coating increases with increasing deposition voltage.

Fig. 7.1 shows the particle size distribution of the material deposited on the workpiece in Example 2 as a function of the deposition voltage at constant dip time (150 seconds). The finer particles are deposited preferentially, with the maximum deposition being of particles of around 20 microns in diameter, and it will be seen that the deposited distribution curve is not much affected by changes in the deposition voltage.

A further series of experiments was conducted at constant deposition voltage (1 kV) but at varying dip times. The results were similar to those shown in Fig. 7.1, i.e., the finer particles are deposited preferentially with a peak at around 20 microns, and the deposited distributions were substantially independent of the dip time.

Fig. 7.2 shows the particle size distribution of the material deposited on the workpiece with a dip time of 60 seconds, as compared with the particle size distribution of the initial powder coating composition.

The results for dip times of 30 seconds, 90 seconds and 120 seconds (not shown in Fig. 7.2) were almost identical.

25

Example 3:

The powder coating composition used in this Example was a brown polyester/TGIC powder designed for corona application and formulated as follows:

30

		<u>Parts by weight</u>
	Rutile Titanium Dioxide	6
	Red Iron Oxide	27
	Yellow Lead Chromate	35
5	Lamp Black 101 Fluffy	12
	Filler (Barium Sulphate)	207
	Carboxylic Acid-Functional Polyester Resin	650
	TGIC	48
10	Flow Modifier	10
	Wax	2
	Benzoin	3
		—
15		991
		—

The ingredients were dry mixed in a blender and fed into a twin-screw extruder operating at a temperature of 20 130°C. The extrudate was ground in an impact mill to produce a powder with the following particle size distribution:

	d(v) ₉₉	101.94 microns
25	d(v) ₅₀	37.62 microns
	10.51%	< 10 microns
	3.98%	< 5 microns

Before fluidisation, the composition was blended with a 0.1% by weight addition of a silica flatting 30 (matting) agent.

The coating process was carried out as described in Example 1, with a workpiece as shown in Fig. 2, except that a constant dip time of 240 seconds was used, and the applied voltage was negative rather than positive.

Table 3 below summarises the characteristics of the finished coating after standard bake and cure as a function of the applied deposition voltage:

Table 3

5

Voltage (Volts) -VE	Time(s)	% Coverage on Recessed Panel		Film Thickness (μm)			Standard Deviation of Film Thickness (μm)
		Outer	Inner	Max.	Min.	Mean	
500	240	0	0	0	0	0	0
1000	240	75	55	37	0	23	13
1500	240	100	80	65	0	44	15
2000	240	100	100	100	55	69	11

25

30

Fig. 8 shows the particle size distribution of the material deposited on the workpiece in Example 3 at a deposition voltage of -2 kV.

35 The particle size distribution of the deposited material may be summarised as follows:

d(v) ₉₉		63.43 microns
d(v) ₅₀		15.13 microns
32.10%	<	10 microns
12.42%	<	5 microns

40

Example 4:

The powder coating composition used in this Example was a white epoxy/polyester hybrid formulated as follows:

5		<u>Parts by weight</u>
	Rutile Titanium Dioxide	352
	Carboxylic Acid-Functional Polyester Resin	317
	Epoxy Resin	314
10	Flow Modifier	10
	Catalyst	1
	Benzoin	3
	Wax	3
15		<hr/>
		996
		<hr/>

The ingredients were dry mixed in a blender and fed into a twin-screw extruder operating at a temperature of 108°C. The extrudate was ground in an impact mill to produce a powder with the following particle size distribution:

	d(v) ₉₉	59.74 microns
25	d(v) ₅₀	21.61 microns
	16.58%	< 10 microns
	5.19%	< 5 microns

Before fluidisation, the composition was blended with 0.75% by weight of a dry flow additive comprising alumina and aluminium hydroxide (45% : 55% by weight).

The coating process was carried out as described in Example 1, with a workpiece as shown in Fig. 2, except that a constant dip time of 150 seconds was used.

Table 4 below summarises the characteristics of the finished coating after standard bake and cure as a function of the applied deposition voltage.

Table 4

Voltage (Volts)	Time (s)	% Coverage on 5mm recessed panel		Film Thickness (μm)			Standard Deviation of Film Thickness (μm)
		Outer	Inner	Max.	Min.	Mean	
0	150	50	90	23	0	10	4
200	150	60	90	24	0	11	4
400	150	95	95	27	0	15	5
600	150	98	99	36	0	25	6
800	150	100	98	47	0	35	7
1000	150	100	100	63	19	43	8

Fig. 9 below shows the particle size distribution of the material deposited on the workpiece in Example 4 at 1kV, as compared with the particle size distribution of the initial coating composition.

The particle size distribution of the deposited material may be summarised as follows:

$d(v)_{99}$	43.15 microns
$d(v)_{50}$	8.08 microns
60.60%	< 10 microns
26.99%	< 5 microns

The results show improved coating performance as compared with the previous Example, and also that, with

the finer initial distribution, the preferential deposition of finer particles (peaking at around 20 microns) leads to less differential depletion of the size distribution of the initial composition.

5

Example 5:

The powder coating composition used in this Example was the same as that used in Example 4, except that the dry flow additive comprising alumina and aluminium hydroxide (45 : 55 w/w) was incorporated in an amount of 0.3% by weight instead of 0.75% by weight.

The coating process was carried out as described in Example 1, with a workpiece as shown in Fig. 2, except that a constant voltage of 1kV was used and the fluidising air pressure was 2 bar.

Table 5 below summarises the characteristics of the finished coating after standard bake and cure as a function of the dip time.

Table 5

20

25

30

Voltage (Volts)	Time (s)	% Coverage on 5mm recessed panel		Film Thickness μm			Standard Deviation of Film Thickness (μm)
		Outer	Inner	Max.	Min.	Mean	
1000	150	100	95	29	3	21	7
1000	240	100	100	33	21	27	4
1000	360	100	100	31	18	23	4

Fig. 10 shows the particle size distribution of the material deposited on the workpiece in Example 5 at 360 seconds, as compared with the particle size distribution of the initial coating composition.

5 The particle size distribution of the deposited material may be summarised as follows:

	$d(v)_{99}$		37.44 microns
	$d(v)_{50}$		12.23 microns
	38.65%	<	10 microns
10	14.02%	<	5 microns

Example 6:

The powder coating composition used in this example was the same as that used in Example 4, except that the 15 composition was blended with 0.3% by weight of aluminium oxide C instead of the aluminium oxide/aluminium hydroxide additive.

The coating process was carried out as described in Example 1, with a workpiece as shown in Fig. 2, except 20 that the fluidising air pressure was 2 bar.

Table 6 below summarises the characteristics of the finished coating after standard bake and cure.

Table 6

25

Voltage (Volts)	Time (s)	% Coverage on 5mm recessed panel		Film Thickness (μm)			Standard Deviation of Film Thickness (μm)
		Outer	Inner	Max.	Min.	Mean	
600	360	100	100	40	25	32	5
700	240	100	98	44	16	32	7
700	360	100	100	42	20	35	6

30

Fig. 11 shows the particle size distribution of the material deposited on the workpiece in Example 6 at 360 seconds, as compared with the particle size distribution of the initial coating composition.

5 The particle size distribution of the deposited material may be summarised as follows:

	d(v) ₉₉		38.94 microns
	d(v) ₅₀		11.65 microns
	43.05%	<	10 microns
10	18.52%	<	5 microns

Example 7:

The powder coating composition used in this Example was the same as that used in Example 4, except that the composition was blended with 0.3% by weight of silica instead of the aluminium oxide/aluminium hydroxide additive.

The coating process was carried out as described in Example 1, with a workpiece as shown in Fig. 2, except that negative voltages were applied to the workpiece and the fluidising air pressure was 2 bar.

Table 7 below summarises the characteristics of the finished coating after standard bake and cure.

Table 7

Voltage (Volts) -VE	Time(s)	% Coverage on 5mm recessed panel		Film Thickness (μm)			Standard Deviation of Film Thickness (μm)
		Outer	Inner	Max.	Min.	Mean	
500	150	100	60	14	0	8	3
1000	150	100	70	23	0	12	4
1250	150	100	95	40	0	21	11
1250	480	100	98	26	0	16	4
1500	150	100	70	31	0	18	5
2000	150	100	80	58	0	33	7
2500	150	100	95	55	0	35	8

Fig. 12 shows the particle size distribution of the material deposited on the workpiece in Example 7 at -1.5 kV and 150 seconds, as compared with the particle size distribution of the initial coating composition.

The particle size distribution of the deposited material may be summarised as follows:

	d(v) ₉₉		37.64 microns
	d(v) ₅₀		9.13 microns
10	55.62%	<	10 microns
	17.58%	<	5 microns

Example 8:

The powder coating composition used in this Example was a grey epoxy/dicyandiamide powder formulated as follows:

	<u>Parts by weight</u>
Rutile Titanium Dioxide	204
Heucosin Fast Blue	5
Lamp Black 101 Fluffy	2
20 Filler (Dolomite)	63
Filler (Barium Sulphate)	84
Epoxy Resin	600
Epicure P-104 (ex.Shell Chemicals)	8
Benzoin	3
25	_____
	1000

30 The ingredients were dry mixed in a blender, and fed into a twin-screw extruder operating at a temperature of 90°C. The extrudate was ground in an impact mill to produce a powder with the following particle size distribution:

35

$d(v)_{99}$ 68.57 microns
 $d(v)_{50}$ 22.67 microns
 14.68% < 10 microns
 5.23% < 5 microns

5 Before fluidisation, the composition was blended with 0.75% by weight of an additive comprising aluminium oxide and aluminium hydroxide (45 : 55 w/w).

The coating process was carried out as described in Example 1, with a workpiece as shown in Fig. 2, but with 10 negative applied voltages and varying the fluidising air pressure.

Table 8 below summarises the characteristics of the finished coating after standard bake and cure.

Table 8

Air Pressure (bar)	Voltage (Volts) -VE	Time (s)	% Coverage on 5mm recess panel		Film Thickness (μm)			Standard Deviation of Film Thickness (μm)
			Outer	Inner	Max.	Min.	Mean	
1	1000	150	98	80	23	0	11	5
	1500	150	100	50	57	0	17	11
	1000	240	100	100	28	3	13	6
	1500	240	100	95	65	0	19	10
	2000	150	100	100	68	4	22	12
	2000	240	100	100	83	4	24	17
2	1000	150	100	99	14	0	9	3
	1000	240	100	95	14	0	10	2
	1500	150	100	95	17	0	12	4
	1500	240	100	100	22	2	12	4
	2000	150	100	95	40	0	22	9
	2000	240	100	98	49	0	22	9

	1500	240	100	80	23	0	16	6
	2000	240	100	100	38	8	24	6

It will be seen that relatively thin films were achievable in this Example.

The particle size distribution of the deposited material may be summarised as follows:

5	d(v) ₉₉	44.65 microns
	d(v) ₅₀	10.66 microns
	45.96%	< 10 microns
	13.08%	< 5 microns

10 Example 9:

The powder coating composition used in this Example was a green polyester/primid powder formulated as follows:

		<u>Parts by weight</u>
15	Yellow Iron Oxide	16
	Lamp Black 101 Fluffy	1
	Monastral Green	19
	Rutile Titanium Dioxide	7
	Carboxylic Acid-Functional	
20	Polyester Resin	570
	Primid XL552 (ex. EMS)	30
	Filler	341
	Benzoin	3
	Flow Modifier	10
25	Wax	3
		—
		993
		—

30

The ingredients were dry mixed in a blender and fed into a twin-screw extruder operating at a temperature of 130°C.

35

- 39 -

The extrudate was ground in an impact mill to produce a powder with the following particle size distribution:

	$d(v)_{99}$		78.7 microns
5	$d(v)_{50}$		26.26 microns
	12.77%	<	10 microns
	5.21%	<	5 microns

Before fluidisation, the composition was blended with 0.3% by weight of an additive comprising aluminium oxide and aluminium hydroxide (45 : 55 w/w).

The coating process was carried out as described in Example 1, except that the substrate was a planar, rectangular aluminium panel (100 mm x 50 mm), a constant dip time of 150 seconds was used, and the applied voltage was varied from + 1kV to - 1kV.

Table 9 below summarises the characteristics of the finished coating after standard bake and cure.

Table 9:

Voltage (Volts)	Time(s)	% Coverage on Flat (100x50)mm Panel	Film Thickness (μm)			Standard Deviation of Film Thickness (μm)
			Max.	Min.	Mean	
0	150	10	14	0	5	4
200	150	70	17	0	9	5
400	150	100	30	6	18	6

-800	150	100	49	31	37	6
-1000	150	100	59	38	45	8

- 40 -

The particle size distribution of the deposited material may be summarised as follows:

	d(v) ₉₉		44.34 microns
	d(v) ₅₀		16.61 microns
5	21.85%	<	10 microns
	7.91%	<	5 microns

Example 10:

The powder coating composition used in this Example 10 was a white hybrid powder formulated as follows:

		<u>Parts by weight</u>
	Rutile Titanium Dioxide	398
	Carboxylic Acid-Functional Polyester Resin	343
15	Epoxy Resin	233
	Flow Modifier	10
	Benzoin	3
	Wax	3
20		—
		990
		—

The ingredients were dry mixed in a blender and fed 25 into a twin-screw extruder at a temperature of 108°C.

The extrudate was ground in an impact mill to produce a powder with the following particle size distribution:

	d(v) ₉₉		89.56 microns
	d(v) ₅₀		32.58 microns
30	7.95%	<	10 microns
	2.56%	<	5 microns

Before fluidisation, the composition was blended with 0.75% by weight of an additive comprising aluminium

oxide and aluminium hydroxide (45 : 55 w/w).

The coating process was carried out as described in Example 1, except that the substrate was a planar, rectangular steel panel (150 mm x 100 mm) pre-treated with zinc phosphate, a constant dip time of 150 seconds was used, and negative voltages were applied to the substrate.

Table 10 below summarises the characteristics of the finished coating after standard bake and cure.

10

Table 10:

Voltage (Volts) -VE	Time(s)	% Coverage on Flat (150x100)mm Panel	Film Thickness (μm)			Standard Deviation of Film Thickness (μm)
			Max.	Min.	Mean	
500	150	100	33	9	21	8
750	150	100	34	7	20	8
1000	150	100	41	7	24	9
1250	480	100	41	6	24	9
1500	150	100	42	10	26	9
1750	150	100	64	27	39	11
2000	150	100	101	20	44	21

30

35

The particle size distribution of the deposited material may be summarised as follows:

	$d(v)_{99}$		51.81 microns
	$d(v)_{50}$		13.40 microns
5	33.97%	<	10 microns
	10.63%	<	5 microns

As is explained above in relation to Example 1, when 3 kV is applied to the workpiece the maximum potential gradient in the fluidising gas is likely to be about 0.79 kV/cm and, for the voltage range of 0.2 kV to 3 kV used in the above Examples, the maximum potential gradient present in any of the Examples is expected to be within the range 0.05 kV/cm to 10 kV/cm.

15 Example 11:

The powder coating composition used in this Example was the same as that used in Example 10.

The substrate was an aluminium extrusion as shown in Figs. 4 and 5. The dimensions of the faces designated 20 d to g in Fig. 4 are as follows:

d : 2.9 cm by 7.5 cm.

e : 3.5 cm by 7.5 cm.

f : 2.9 cm by 7.5 cm.

g : 2.3 cm by 7.5 cm.

25 Considering the common dimension of 7.5 cm as the height of the substrate shown in Figs. 4 and 5, the substrate would fit into a rectangular "tube" of height 7.5 cm, width 4.5 cm and depth 3.9 cm. When positioned centrally and upright in a Nordson Corporation 30 cylindrical fluidisation unit of 15 cm diameter, the minimum spacing between the substrate and the wall of the fluidisation unit would be about 4.4 cm, resulting in a maximum potential gradient between the substrate and the fluidisation unit of about 0.23 kV/cm when the

voltage applied to the substrate is 1 kV. Air serves as the fluidising gas and a maximum potential gradient of 0.23 kV/cm is well below the ionisation potential gradient of 30 kV/cm for air at atmospheric pressure. That is, the maximum potential gradient present in the apparatus used in the experiment is expected to lie below 1 kV/cm. When the voltage applied to the substrate is 1 kV, the substrate would need to come within 0.033 cm of the wall of the fluidisation unit for the maximum potential gradient to reach 30 kV/cm. Allowing for oscillation or vibration of the workpiece, it is expected that the conditions would result in maximum potential gradients in the range 0.05 kV/cm to 10 kV/cm, as stated above.

15 The coating process was carried out as described in Example 1 with a dip time of 150 seconds at 1kV.

Approximately 100% coverage of the substrate was achieved after standard bake and cure (including coverage of the inner surfaces of the void (12) and of the various illustrated recesses) with film thickness as follows on the faces designated d to g:

	<u>d</u>	51 microns
	<u>e</u>	42 microns
	<u>f</u>	47 microns
25	<u>g</u>	53 microns

Referring to Fig. 13 of the accompanying drawings, the second form of fluidisation and coating apparatus comprises a fluidisation chamber indicated generally by the reference numeral (13) having walls composed alternately of insulating sections (14a,14b,14c) and conducting sections (15a,15b). End sections (16a,16b) of the fluidising chamber are also conducting. The conducting sections 16a, 15a, 15b and 16b are connected to respective voltage sources V1, V2, V3 and V4.

In operation, a fluidised-bed of a powder coating composition is established within the fluidisation chamber (13) and a series of workpieces (17,18,19) is immersed and transported through the bed in a direction 5 shown (by means not shown). Each workpiece shown in Fig. 13 is of the form shown in Fig. 2, but the apparatus can in principle be used to coat articles of any desired shape.

For at least part of the period of immersion, the 10 workpieces are electrically charged by means of direct voltages in such a way that the polarities of successive workpieces are in alternating sequence. The alternating polarities of the workpieces and the voltages applied to the conducting sections 15a, 15b, 16a and 16b of the 15 wall of the fluidising chamber 13, along with the bipolar charging of the powder particles, result in the workpieces being subjected to a sequence of conditions as they pass through the fluidising chamber. The conducting sections 15a, 15b, 16a and 16b may, 20 alternatively, be all connected to the earth terminal of the mains supply rather than to voltage sources.

Referring to Figs. 14 and 15 of the accompanying drawings, an arrangement 20 used in carrying out Example 12, described below, includes side (as viewed) pillars 25 21 of electrically insulating material, upper and lower (as viewed) steel bars 22 and 23, a corrugated steel panel 24, a steel front (as viewed) plate 25, a steel rear (as viewed) plate 26, a plurality of securing bolts 27 holding the steel plates 25 and 26 firmly together 30 with the corrugated steel panel 24 between the steel plates 25 and 26, a first plurality of steel rods 28 passing through front (as viewed) recesses of the corrugated steel panel 24 in addition to passing through apertures in the steel bars 22 and 23 and a second

plurality of steel rods 29 passing through rear (as viewed) recesses of the corrugated steel panel 24 in addition to passing through apertures in the steel bars 22 and 23. The ends of the steel rods 28 and 29 are threaded and nuts screwed along the threaded ends of the steel rods 28 and 29 securing them to the upper and lower steel bars 22 and 23. The side pillars 21 are attached to the upper and lower steel bars 22 and 23, forming a rigid frame. The side pillars 21 are also securely clamped between the front and rear steel plates 25 and 26 by threaded bolts secured by nuts. The arrangement 20 is a rigid assembly in which the front plate 25, the rear plate 26 and the corrugated panel 24 form a first conductive sub-assembly while the upper bar 22, the lower bar 23 and the rods 28, 29 form a second sub-assembly. The first and second sub-assemblies are isolated electrically from each other by the non-conductive pillars 21 and no parts of the two sub-assemblies contact one another.

The corrugated panel 24 includes corrugations of a maximum depth of 4 cm and the dimensions of the panel 24 are 30 cm (length) by 18 cm (height). The corrugated panel 24 serves as the workpiece and the rods 28, 29 serve as counter-electrodes in Example 12 described below.

The arrangement 20 is 4 cm thick and its overall dimensions are 42 cm (length) by 24 cm (height). The front and rear plates 22 and 23 are each 18 cm high.

Example 12:

The powder coating composition used in this Example was a white epoxy/polyester hybrid formulated as in Example 4. The ingredients were dry mixed in a blender and fed into a twin screw extruder operating at a

temperature of 108 C. The extrudate was ground in an impact mill to produce a powder with the following particle size distribution:

5 $d(v)_{99} = 55$ microns
 $d(v)_{50} = 22$ microns
 16% < 10 microns
 5% < 5 microns

Before fluidisation, the powder was blended with 0.6% by weight of a dry flow additive comprising alumina 10 and aluminium hydroxide (45%:55% by weight).

The coating process was carried out as follows on the frame described above with reference to Figs. 14 and 15:

A rectangular fluidising vessel of dimensions 80 cm 15 (length) by 40 cm (width) by 50 cm (height) was filled to three-quarters of its height with the powder described above and the powder was fluidised using compressed air at a pressure of 4 bar. The panel 24 and the front and rear plates 25, 26 were connected to a 20 positive voltage of 2 kV. The upper bar 22 was connected to the earth terminal of the mains supply, maintaining the upper bar 22, the lower bar 23 and the rods 28, 29 at earth relative to the panel 24 and the plates 25, 26.

The minimum distance between the rods 28, 29 and 25 the panel was measured as 3 mm, giving a maximum potential gradient of 6.67 kV/cm between the charged and the earthed parts, well below the level of 30 kV/cm that would result in corona effect or ionisation in the fluidised bed. The maximum potential gradient of 6.67 30 kV/cm lies within the range 0.05 kv/cm to 10 kV/cm given above.

The arrangement 20 including the workpiece 24 and the counter-electrodes 28, 29 was immersed vertically in the fluidised-bed for a time of 300 seconds during which

the arrangement 20 was subjected to front-to-back oscillatory motion and, also, a vertical dipping motion, maintaining powder fluidity in the recesses of the workpiece 24. The process was carried out three times with different numbers of rods 28, 29 as described in the following three experiments. At the end of each experiment, the workpiece 24 was removed and subjected to a standard bake and cure. The remaining apparatus was thoroughly cleaned of deposited powder and reassembled along with a replacement workpiece 24.

Experiment 1

The second plurality of rods 29 were included without the first plurality of rods 28. At the end of the coating period, there was found to be 100% coverage of the rear recesses (as viewed) in the workpiece 24 facing the second plurality of rods 29. In the front recesses (as viewed) where the first plurality of rods 28 had been omitted, the workpiece 24 was found to be coated only to a depth of 4 cm below the upper edge and above the lower edge, the coating ending abruptly. The remainder of the front (as viewed) of the workpiece 24 was bare except for some specks of powder indicating virtually no powder deposition.

Experiment 2

Only half of the second plurality of rods 29 were included and so distributed that rod-present recesses alternated with rod-absent recesses. After the coating process was completed, those recesses in which rods had been present were found to be fully coated while there was coating in the recesses where there had been no rods only to 4 cm below the upper edge and above the lower edge of the workpiece 24. The front of the workpiece 24 was as for Experiment 1 above.

Experiment 3

Both the first and the second plurality of rods 28, 29 were included providing a rod in every recess in the workpiece 24. Full coating was achieved in both the front and rear recesses, the only bare areas being those which were in contact with the front and rear plates 25, 26.

The perceived advantage of the process described above is that the presence of the earthed counter-electrodes in the recesses so influences the electric field around the workpiece as to cause the electric field to extend fully into the recesses whereas, without the earthed counter-electrodes, the electric field penetrates only slightly into the recesses. The improved penetration of the electric field into the recesses leads to improved penetration of the powder. The full penetration into narrow recessed parts, as is demonstrated with this process, is important to prevent corrosion in narrow recesses parts and is difficult or even impossible to achieve with conventional coating processes.

Referring to Fig. 16 of the accompanying drawings, an arrangement 30 used in carrying out Example 13, described below, includes a bar 31 carrying holders 33, 34 for a workpiece and counter-electrodes, respectively, and guides 32 for mounting the bar 31 on a fluidising chamber (not shown).

Referring to Fig. 17 of the accompanying drawings, the arrangement 30 of Fig. 16 is shown mounted on a fluidising chamber 38 provided with an air input port 37. In Fig. 17, the arrangement 30 of Fig. 16 is shown as carrying a plate-like workpiece 36 and flanked by plate-like counter-electrodes 35.

Example 13

The powder coating composition used in this Example was a white epoxy/polyester hybrid formulated as in Example 4. The ingredients were dry mixed in a blender 5 and fed into a twin screw extruder operating at a temperature of 108 °C. The extrudate was ground in an impact mill to produce a powder with the following particle size distribution:

	$d(v)_{99} =$	59 microns
10	$d(v)_{50} =$	25 microns
	9%	< 10 microns
	3%	< 5 microns

Before fluidisation, the composition was blended with 0.25%, by weight, of a dry flow additive comprising 15 alumina and aluminium hydroxide (45%:55% by weight).

The coating process was carried out as follows using the apparatus described above with reference to Figs. 16 and 17:

The rectangular fluid bed 38 of dimensions 80 cm 20 (length) by 40 cm (width) by 50 cm (height) was filled to three-quarter height with the above powder and fluidised at a pressure of 4 bar. A planar, rectangular aluminium panel of dimensions 15 cm by 10 cm, serving as the workpiece 36, was charged positively and immersed in the 25 fluidised-bed for up to 150 seconds, the workpiece 36 being positioned between two negatively charged plates serving as counter-electrodes 35. The charged workpiece 36 was given a side-to-side motion for the duration of its immersion.

30 The perceived advantage of this process is the enhancement of the electric field between the workpiece 36 and the counter-electrodes 35 at the expense of the field between the workpiece 36 and the earthed walls of fluidising chamber 38. The reduction in the field between

the workpiece 36 and the walls of the fluidising chamber 38 results in a reduction in the undesirable accumulation of powder on the walls of the fluidising chamber 38.

Table 11, below, summarises the characteristics of the finished coating after a standard bake and cure as a function of the voltages applied to the workpiece 36 and the counter-electrodes 35, demonstrating the influence of the counter-electrodes.

Table 11

CLAIMS:

1. A process for forming a coating on a conductive substrate, which comprises establishing a fluidised bed of a powder coating composition, immersing
5 the substrate wholly or partly within the said fluidised bed, applying a voltage to the substrate for at least part of the period of immersion, whereby particles of the powder coating composition adhere to the substrate, withdrawing the substrate from the fluidised bed and
10 forming the adherent particles into a continuous coating over at least part of the substrate.
2. A process as claimed in claim 1, wherein the substrate comprises metal.
3. A process as claimed in claim 1 or claim 2,
15 wherein the applied voltage is a direct-current voltage.
4. A process as claimed in any one of claims 1 to 3, for coating successive substrates in sequence, in which direct-current voltage is used and the polarity of the voltage applied to successive
20 substrates is reversed from each substrate to the next so as to produce an alternating sequence.
5. A process as claimed in claim 4, which is a continuous process in which a series of substrates of alternate polarities is transported through a fluidised
25 bed established within a fluidising chamber having walls composed alternately, in the direction of travel of the substrates, of insulating sections and conducting sections.
6. A process as claimed in any one of claims 1
30 to 3, which comprises the simultaneous batchwise coating of one or more pairs of substrates disposed within a common fluidised bed, the substrates of each pair being charged by direct-current voltages to respectively opposite polarities.

7. A process as claimed in any one of claims 1 to 6, wherein the fluidised bed is established within an earthed vessel.

8. A process as claimed in any one of claims 1 to 7, in which one or more counter-electrodes, preferably earthed, are disposed within the bulk of the powder coating composition.

9. A process as claimed in any one of claims 1 to 8, wherein there is no earth connection to the substrate.

10. A process as claimed in any one of claims 1 to 9, wherein the substrate is wholly immersed within the fluidised bed.

11. A process as claimed in any one of claims 1 to 10, wherein there is no preheating of the substrate prior to immersion in the fluidised bed.

12. A process as claimed in any one of claims 1 to 11, wherein the powder coating composition is a thermosetting system.

20 13. A process as claimed in any one of claims 1 to 12, wherein the powder coating composition incorporates, by dry-blending, one or more fluidity-assisting additives.

14. A process as claimed in claim 13, wherein the powder coating composition incorporates a combination of alumina and aluminium hydroxide as fluidity-assisting additive.

15. A process for coating a conductive substrate which comprises an automotive or aerospace component, in which a first coating derived from a powder coating composition is applied by means of a process according to any one of claims 1 to 14, and thereafter a topcoat is applied over the powder coating.

16. Apparatus for use in a process as claimed in any one of claims 1 to 15 for forming a coating on a conductive substrate, which comprises:

- (a) a fluidising chamber;
- (b) means for effecting fluidisation of a bulk powder coating composition within the fluidising chamber so as to establish a fluidised bed of the composition therein;
- (c) means for immersing a substrate wholly or partly within
10 the fluidised bed;
- (d) means for applying a voltage to the substrates for at least part of the period of immersion, whereby the substrate becomes electrically charged so that particles of the powder coating composition adhere
15 thereto;
- (e) means for withdrawing the substrate bearing adherent particles from the fluidised bed; and
- (f) means for converting the adherent particles into a continuous coating.

20 17. A substrate whenever coated by a process as claimed in any one of claims 1 to 15 or by means of an apparatus as claimed in claim 16.

18. A process as claimed in any one of claims 1 to 15, wherein the voltage applied to the substrate is
25 such that the maximum potential gradient existing in the fluidised bed lies substantially below the ionisation potential gradient for the gas in the fluidised bed.

19. A process as claimed in any one of claims 1 to 15 or 18, wherein the maximum potential gradient
30 existing in the fluidised bed lies between 0.05 kV/cm and 10 kV/cm., both limits included.

20. A process as claimed in claim 19, wherein the maximum potential gradient existing in the fluidised bed lies between 0.05 kV/cm and 5 kV/cm., both limits included.

5 21. A process as claimed in claim 20, wherein the maximum potential gradient existing in the fluidised bed lies between 0.05 kV/cm and 1 kV/cm., both limits included.

22. A process as claimed in any one of claims 1 to 10 15 or 18 to 21, wherein the voltage applied to the substrate lies between 5 kV and 60 kV, both limits included.

23. A process as claimed in claim 22, wherein the voltage applied to the substrate lies between 15 kV and 15 35 kV, both limits included.

24. A process as claimed in claim 23, wherein the voltage applied to the substrate lies between 5 kV and 30 kV, both limits included.

25. A process as claimed in claim 22, wherein the 20 voltage applied to the substrate lies between 30 kV and 60 kV, both limits included.

26. A process as claimed in any one of claims 1 to 15 or 18 to 25, wherein the particles of the powder coating composition vary in size between 1 and 120 25 microns, both limits included.

27. A process as claimed in claim 26, wherein the particles vary in size between 15 and 75 microns, both limits included.

28. A process as claimed in claim 27, wherein the 30 particles vary in size between 25 and 50 microns, both limits included.

29. A process as claimed in claim 28, wherein the particles vary in size between 20 and 45 microns, both limits included.

30. A process as claimed in any one of claims 1 to 15 or 18 to 29, wherein the substrate receives a coating of thickness between 5 and 200 microns, both limits included.

5 31. A process as claimed in claim 30, wherein the substrate receives a coating of thickness between 5 and 100 microns, both limits included.

32. A process as claimed in claim 30, wherein the substrate receives a coating of thickness between 10 and 10 150 microns, both limits included.

33. A process as claimed in claim 32, wherein the substrate receives a coating of thickness between 20 and 100 microns, both limits included.

34. A process as claimed in claim 33, wherein the 15 substrate receives a coating of thickness between 60 and 80 microns, both limits included.

35. A process as claimed in claim 33, wherein the substrate receives a coating of thickness between 80 and 100 microns, both limits included.

20 36. A process as claimed in claim 31, wherein the substrate receives a coating of thickness between 50 and 150 microns, both limits included.

37. A process as claimed in claim 32, wherein the substrate receives a coating of thickness between 15 and 25 40 microns, both limits included.

38. A process as claimed in any one of claims 1 to 15 or 18 to 37, wherein less than 10 mA flows in the substrate.

39. A process as claimed in claim 38, wherein less 30 than 5 mA flows in the substrate.

40. A process as claimed in claim 39, wherein less than 1 mA flows in the substrate.

41. A substrate whenever coated by a process as claimed in any one of claims 18 to 40.
